Introduction

Other Topics

- In addition to *intrinsic data types* (integer, real, complex, logical, character), Fortran 90/95 and newer allow the programmer to create *user-defined data types*
- Motivation: group together all the information about a particular item (similar to `struct` in C/C++, but also allows for object-oriented programming in Fortran 2003 and newer)
- Use the keyword `TYPE` to create a derived data type following the form below:

```
TYPE [::] type_name
    component definitions
    ...
END TYPE [type_name]
```

# Example: Linear System

- Let us define a type to represent a linear system  $Ax = b$ , where  $A$  is an *allocatable* matrix, and  $x$  and  $b$  are *allocatable* vectors

```
TYPE :: LinearSystem
  INTEGER :: n ! Problem size
  REAL, ALLOCATABLE, DIMENSION(:, :) :: A ! Matrix of
    coefficients
  REAL, ALLOCATABLE, DIMENSION(:) :: x ! Solution
    vector
  REAL, ALLOCATABLE, DIMENSION(:) :: b ! Vector with
    RHS elements
END TYPE LinearSystem
```

- To create variables of the type `LinearSystem`, just do:

```
TYPE (LinearSystem) :: ls1, ls2 ! Two variables of type
  LinearSystem
TYPE (LinearSystem), DIMENSION(10) :: lss ! Array of 10
  LinearSystems
```

# Working with Derived Data Types

- Each component (field) of a derived data type is accessed with the *component selector* (%)
- Suppose the variable `ls1` is of type `LinearSystem`, then we can set its component `n` to the value 5 as follows:

```
ls1%n = 5
```

- Suppose the variable `lss` is an array of 10 `LinearSystems`, then we can set the component `b` of its 3<sup>rd</sup> element to a predefined vector as follows:

```
REAL(KIND = REAL64), DIMENSION(9) :: b

b = (/ 1, 2, 3, 4, 5, 4, 3, 2, 1 /)
ALLOCATE(lss(3)%b(9))
lss(3)%b = b
WRITE(*,*) lss(3)%b
DEALLOCATE(lss(3)%b)
```

# Restricting Access I

Derived Data  
Types in  
Fortran

Front Matter

Table of  
Contents

Introduction

Other Topics

- You can restrict access to the contents of a `MODULE` and the components of a `TYPE` by using the keywords `PRIVATE` and `PUBLIC`. Private data are not accessible outside the current program unit (main programs, subroutines, and functions)
- Examples:

```
TYPE :: vector
  PRIVATE
  REAL :: x, y
END TYPE vector
```

The type `vector` as a whole is still available outside the program unit, but its components `x` and `y` *cannot* be accessed separately

# Restricting Access II

- An entire derived data type can be declared to be private:

```
TYPE, PRIVATE :: vector
    REAL :: x, y
END TYPE vector
```

The type `vector` is not accessible by any program units that use the module containing it

- Declaring private variables:

```
TYPE :: vector
    REAL :: x, y
END TYPE vector
TYPE (vector), PRIVATE :: vec
```

The type `vector` is public, but the variable `vec` may be used only within the module containing it

# Object-Oriented Programming (OOP)
